

A Dosimetric Study of Volumetric Arc Modulation with RapidArc Versus Intensity-modulated Radiotherapy in Cervical Cancer Patients

BRIJESH GOSWAMI¹, RAKESH KUMAR JAIN², SURESH YADAV³, SUNIL KUMAR⁴, SAJI OOMMEN⁵, SAPNA MANOCHA⁶, GANESH K JADHAV⁷

ABSTRACT

Introduction: The method of radiotherapy has moved away from two-dimensional and three-dimensional conformal radiotherapy towards Volumetric-Modulated Arc Therapy (VMAT) for advanced carcinomas. VMAT treatments often result in significant clinical advantage, particularly when concave dose distributions are required as is often the situation since these tumours are in close proximity to several critical structures.

Aim: To investigate the potential clinical role of volumetric arc therapy on cervical cancer patients and its comparison with fixed-field Intensity-Modulated Radiotherapy (IMRT) was used as a benchmark.

Materials and Methods: This retrospective study was conducted on 15 cervical cancer patients selected for radiotherapy treatment. These patients were previously treated with sliding window IMRT techniques during January 2020 to November 2020. For dosimetric comparison of sliding window IMRT techniques with RapidArc, a new set of plans were created using VMAT/RapidArc technique. For each patient two plans were generated and in this way total 30 plans were analysed. The prescription dose to Planning Target Volume (PTV) was 50.4 Gy in 28 fractions (1.8 Gy/fraction) for the 6 MV photon beam. Comparison of each plan done on the basis of Organs at Risk (OAR) sparing, coverage index (C), Conformity Index (CI), Homogeneity Index (HI), dose Gradient Index (GI), and Unified Dosimetry Index (UDI). This study utilised UDI scoring for evaluation and comparison of RapidArc and IMRT

plans. Treatment Time (TT) for patient comfort and the number of Monitor Units (MUs) for long-term side-effects was also taken into consideration. A paired two-tailed t-test was executed for the dosimetric study of volumetric arc modulation with RapidArc and its comparison with the IMRT technique in the radiotherapy treatment of cervical cancer patients. All the collected data was analysed using Statistical Package for Social Sciences (SPSS) version 20.0. The p-value <0.05 was contemplated for the level of statistical significance.

Results: Comparable target coverage and better sparing of OARs were achieved with the RapidArc technique in comparison to IMRT. It was evident with results of present study, the values of CI (1.55±0.07), HI (1.07±0.07), GI (0.98±0.01) and UDI (1.25±0.11) of RapidArc technique showed significant difference from respective values of IMRT Technique (1.67±0.06, 1.10±0.06, 0.96±0.01 and 1.38±0.13). Values of MUs (1560.47±52.16) and treatment time (3.71±0.73 mins) were significantly high in IMRT technique as compared to RapidArc technique (542.33±51.09 and 2.39±0.35 mins respectively).

Conclusion: From this study, it is clear that a similar planning goal can be achieved by RapidArc in comparison to fixed-field IMRT with less normal organ toxicity. RapidArc is a faster and precise treatment technique. The most significant change comes to see in the number of MUs and TT, which is much lesser in RapidArc.

Keywords: Conformity index, Gradient index, Homogeneity index, Unified dosimetry index

INTRODUCTION

Cervical cancer is a widespread type of cancer all around the world [1-3]. Radiotherapy is the treatment of choice for definitive and postoperative management of cervical and endometrial cancer [4-7]. According to the staging of cancer, pelvic lymph node also include apart from the primary area. Due to this acute and late complications occur in genitourinary and gastrointestinal areas. The main principle of radiotherapy is providing a high dose to the tumour but as low as a reasonably achievable dose to the normal healthy organs to reduce long-term side-effects. Good tumour coverage can be achieved by normal conventional techniques but at the cost of higher OARs doses. Due to all these complications need for usage of advanced technology in treatment increased, these modern techniques can provide better target coverage and good sparing of OARs also. For these techniques, a plan quality can be analyzed by using many dosimetric indices. An ideal plan is defined as one with full uniform dose coverage, exactly conformed to the target, and stepwise fall off dose outside the target [8-11]. Akpati H et al.,

came with a new idea called a Unified Dosimetry Index (UDI) [12]. UDI scoring includes all four dosimetric indices such as coverage index (C), CI, HI, and dose GI. UDI scoring of every plan ranked and preferred the least scored plan as a better plan. Regarding the UDI, very little data is available for review.

The basic principle of IMRT is to radiate target from multiple directions to get a conformal dose to target and at the same time low dose to normal organs [13-16]. IMRT significantly reduces doses to bladder, bowel, and rectum in comparison to traditionally used techniques [17-21]. Fixed-field IMRT has a large beam-on time, due to this it takes a longer time to treat any patient. The number of MUs is also very large in IMRT techniques. The volumetric-arc therapy (VMAT or RapidArc) has capability to treat patients by gantry rotation in 360°. Limitations of IMRT plans can be easily overcome with arc technique and able to achieve more conformal dose in lesser time with lesser MUs. The primary algorithm of VMAT for planning and delivery was developed by Otto's study [22]. RapidArc (Varian Medical System, Palo Alto, CA)

allows continuous variation in gantry rotation speed, dose rate, and dynamic Multileaf Collimators (MLCs) during treatment [23]. These techniques can give single and multiple arcs with a variable dose rate [24]. Arc therapy has been applied for the various sites of the body like the prostate, oesophagus, cervix, and brain tumours [25,26]. Various studies suggested that better target coverage and better OARs are sparing in RapidArc [27].

This study utilised UDI scoring for evaluation and comparison of RapidArc and IMRT plans in the case of cervical cancer. The primary aim for this study was to investigate whether Eclipse Treatment Planning System (TPS) was capable of generating RapidArc plans with dose distributions that would have been clinically accepted if they had been generated by standard clinical IMRT.

MATERIALS AND METHODS

This was the retrospective study done on data of 15 patients treated for cervical cancer at a tertiary care centre at Indraprastha Apollo Hospital, New Delhi. These patients were previously treated with sliding window IMRT techniques during January 2020 to November 2020.

Inclusion criteria: Data of patients of locally advanced carcinoma of the cervix with their International Federation of Gynaecology and Obstetrics (FIGO) stage IB-IIIB, who were earlier treated within the Department of Radiotherapy, Indraprastha Apollo Hospital, New Delhi during January 2020 to November 2020 on Novalis-Tx (Varian Linear Accelerator) with sliding window IMRT techniques were selected for this study [24].

Exclusion criteria: The patients beyond the FIGO staging range IB-IIIB were excluded from this study.

Patients were positioned with an immobilisation mask system. Continuous 3 mm Computed Tomography (CT) scans of the pelvis cancer patients were obtained with a spiral CT scanner (Siemens Biograph) in the supine position. Dose prescription to the PTV was 50.4 Gy in 28 fractions. The prescribed doses were given in 28 fractions (1.8 Gy/fraction), one fraction per day, and 5 fractions per week. Optimisation constraints for PTV and OARs were based on the Radiation Therapy and Oncology Group (RTOG) 0724 protocol [28].

Treatment Planning and Delivery

All techniques were generated by using Eclipse version 13 (Varian Medical Systems, Palo Alto, CA, USA) Treatment Planning System (TPS). The calculations were done with the High Definition (HD)-120 MLC. The plans were calculated with 6 MV photons. The number of fields was 9 for IMRT with 600 MU/min dose rate. For RapidArc, the triple arc (CW, CCW, and 90° CW) treatment field was split into 178 control points. The beam aperture was defined for each control point by MLC changes and gantry angle. The dose rate varied between 100 MU/min and a maximum of 600 MU/min. The algorithm used for planning purposes was Anisotropic Analytical Algorithm (AAA) [29-33]. During the RapidArc optimisation, the standard clinical IMRT objectives, in terms of target coverage and dose to OARs were used.

Plan Evaluation Parameters

Evaluation of plans was performed utilising standard Dose-Volume Histograms (DVHs). For PTV minimum, mean, and maximum doses were evaluated. According to the International Commission on Radiation Units and Measurements (ICRU) report 83 [34], $D_{98\%}$ (minimum dose received by 98% of PTV volume) and $D_{2\%}$ (maximum dose received by 2% of PTV volume) dose-volume parameters were evaluated for PTV. Apart from D_{max} and D_{mean} , V_{40Gy} parameters were also evaluated for rectum and bladder. For small bowel, D_{mean} and D_{200cc} parameters were taken into considerations. Numbers of MUs and TT were also evaluated for patient comfort and long-term

side-effects. Other calculated parameters were CI, HI, GI, coverage index (C), and UDI.

STATISTICAL ANALYSIS

Statistical Software Package for the Social Sciences (SPSS) version 20.0 (IBM Corporation, USA) was used for statistical analysis. Descriptive analysis was performed to determine the mean and Standard Deviation (SD) value of different dose-volume parameters of target, OARs and different dosimetric indices. A paired two-tailed t-test was performed to compare the IMRT technique with the RapidArc technique for radiotherapy treatment of cervical cancer patients. The p-value <0.05 was considered for the significance of statistical inferences.

Dose coverage is defined as 100% of the PTV receiving the prescribed dose. It gives a measure of how well the PTV is covered by the prescribed dose. A plan covered by 92% of prescribed dose is considered acceptable [35].

$$\text{Coverage Index (C)} = \text{PTV}_{PI} / \text{PTV}$$

Where, PTV_{PI} is the PTV receiving the Prescribed Isodose (PI).

The CI was first proposed in 1993 by RTOG and described in Report no. 62 of ICRU [36]. It is presented as a relation between the volume of the reference dose and target volume.

$$\text{Conformity Index (CI)} = V_{IR} / \sqrt{TV}$$

Where, V_{IR} is the volume of reference dose and TV is the target volume.

According to the RTOG guidelines [37], ranges of CI values have been defined to determine the quality of conformation. Theoretically, 1 is an ideal value for CI. If the CI is situated between 1 and 2, the treatment is considered to comply with the treatment plan.

In 1993, RTOG proposed guidelines for routine evaluation of plans on several parameters and HI. The concept of HI was developed as an extension of the dosimetric analysis of the treatment plan.

$$\text{Homogeneity Index (HI)} = I_{max} / RI$$

Where, I_{max} is maximum isodose in the target, and RI is the reference isodose.

If the HI value is ≤ 2 , treatment is considered to comply with the protocol, if this index is between 2 to 2.5, it is considered as a minor violation, but if the index exceeded 2.5, the violation of the protocol is considered to be major, but might nevertheless considered acceptable [38].

The dose GI can compare the plan of equal conformity but with different dose gradients. The quality of this dose gradient is quantified by GI. The dose GI is defined as the ratio of the volume receiving the PI line and the dose-volume receiving half of the PI line [39,40].

$$\text{Dose gradient index (GI)} = DV_{PI} / DV_{HPI}$$

Where, DV_{PI} is the dose-volume of the PI; DV_{HPI} is the dose volume of the half the prescribed dose.

The UDI consists of all four parameter that are described above [12]. It is a useful tool to decide on a perfect plan. For any perfect planning, all value of CI, HI, GI, and C should also be perfect. Change in any of the four components may change the value of UDI. UDI value close to 1 is desirable whereas a higher value of UDI is not desirable. Perfect planning have UDI value one [41]. All the four parameters have equal weightage in any planning so that UDI define as:

$$\text{UDI} = \text{CI} \times \text{C} \times \text{HI} \times \text{GI}$$

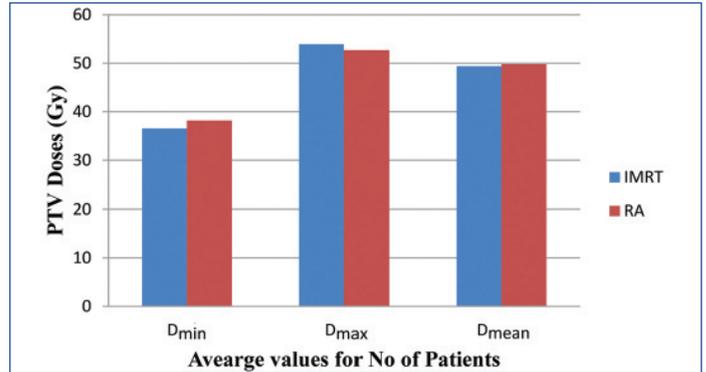

RESULTS

The colour wash of different doses in axial, coronal, and sagittal is shown in [Table/Fig-1]. From dose distribution, it can easily find out there is a dose reduction in the bladder and rectum in RapidArc plan.

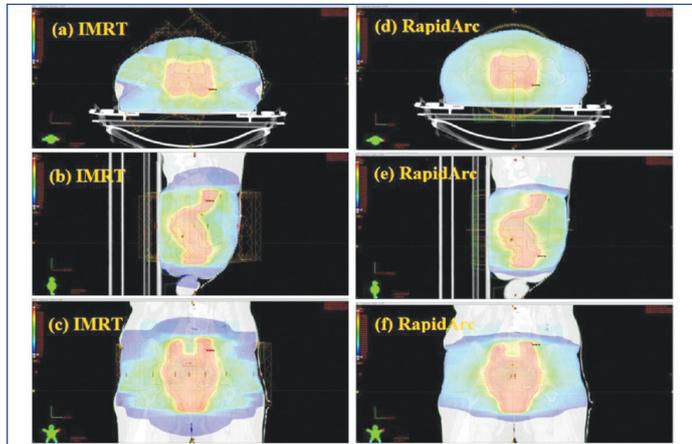

The same type of dose distribution was obtained for other patients also. Dosimetric assessments of both the treatment techniques are tabulated in [Table/Fig-2-4]. Doses to bladder, rectum, and small bowel were within the tolerance limit for both the plans as per recommended by RTOG guideline P0126 [42]. But from the [Table/Fig-2,3], it was clear that results were in favour of the RapidArc plan in respect to better OARs sparing at the cost of good PTV coverage as shown in [Table/Fig-5,6]. [Table/Fig-4] shows that number of MUs used by the IMRT plan was three times higher than Rapid plan (1560.47±52.16 for IMRT and 542.33±51.09 for RapidArc). Due to this, overall TT significantly increased for the IMRT plan, which was around 1.5 times higher than the RapidArc plan (3.71±0.73 for IMRT and 2.39±0.35 for RapidArc) [Table/Fig-7]. In the present study, a plan quality analyses by using different dosimetric indexes like HI, CI, ID, C, and UDI. The mean value of CI, HI, GI, and C for RapidArc plan were 1.55±0.07, 1.07±0.07, 0.98±0.01, and 0.78±0.03, respectively. The same index values for the IMRT plan were 1.67±0.06, 1.10±0.06, 0.96±0.01, and 0.78±0.04, respectively [Table/Fig-4]. From the above value of CI, HI, GI, and C it is clear that RapidArc plans are better in all the parameters [Table/Fig-8]. In Results of this UDI scoring are also in favour RapidArc plan (1.25±0.11 for RapidArc plans and 1.38±0.13 for IMRT plans).

Parameters	Treatment techniques		p-value (Paired t-test)
	IMRT (Mean±SD)	RapidArc (Mean±SD)	
Treatment Time (min.)	3.71±0.73	2.39±0.35	<0.001
Number of Monitor Units (MUs)	1560.47±52.16	542.33±51.09	<0.001

DISCUSSION

RapidArc therapy trial gives a large degree of freedom by providing many control points (178) for dynamic dose delivery during gantry rotation. In comparison to RapidArc, IMRT plans provide dose delivery only at fixed beam angles only. Due to this, IMRT plans may skip some best possible beam angles during dose delivery. This type of problem can be easily overcome by using RapidArc [42]. Many supporting studies have been provided their results in favour of fixed-field IMRT in comparison to conventional planning techniques [17-21]. Oliver M et al., and Nicolini G et al., studies show that at the same PTV coverage, RapidArc can generate a plan with better homogeneity and conformity [43,44]. There is a significant reduction in doses for rectum, small bowel, and bladder.

RapidArc uses all feasible angles for optimisation to generate the best possible plan at a prescribed dose to PTV and doses to OARs accordingly [45]. An extra arc can be easily used for complex and large target volume like gynecological tumours because the numbers of MUs and TT significantly increased if authors used IMRT techniques for the same type of patients. In such a case, a RapidArc technique is a better alternative than fixed-field IMRT techniques. GI is also improved with the RapidArc plan which shows dose fall off. UDI scoring is a good technique for comparing multiple plans. It can help in deciding a better plan in respect of many parameters. A lower value of UDI shows a better

plan. Results show that both the techniques can generate clinically acceptable plan but RapidArc gives better values compared to IMRT techniques.

Limitation(s)

This dosimetric study was retrospective in nature and performed with only fifteen patients of cervical cancer.

CONCLUSION(S)

A RapidArc technique shows better target coverage, homogeneity, and conformity in comparison with fixed-field IMRT techniques. There is a sharper dose fall-off for the RapidArc plan with a comparative dose to surrounding organs like bowel rectum and bladder. These all parameters combined and give better UDI scoring in favour of RapidArc. The potential benefit of Rapid Arc in respect of patient comfort is shorter TT and in long-term side-effect is lesser MUs. This study shows that a RapidArc can be an alternative where it's required in favour of patient comfort as well as clinically benefit also. A prospective study should be performed with larger data set to validate the recommendations of this study.

PARTICULARS OF CONTRIBUTORS:

1. Research Scholar, Department of Physics, Shobhit Institute of Engineering and Technology, Meerut, Uttar Pradesh, India.
2. Professor, Department of Physics, Shobhit Institute of Engineering and Technology, Meerut, Uttar Pradesh, India.
3. Assistant Professor Medical Physics, Department of Radiation Oncology, Gandhi Medical College, Bhopal, Madhya Pradesh, India.
4. Medical Physicist, Department of Radiotherapy, Indraprastha Apollo Hospital, New Delhi, India.
5. Medical Physicist, Department of Radiotherapy, Indraprastha Apollo Hospital, New Delhi, India.
6. Radiation Oncologist, Department of Radiotherapy, Indraprastha Apollo Hospital, New Delhi, India.
7. Radiation Oncologist, Department of Radiotherapy, Indraprastha Apollo Hospital, New Delhi, India.
